## Explanation of Results

1. This test shows the response time of your web hosting. This is different from the load time of your webpage. The load time of your webpage depends on several factors, including its code, caching, content delivery system and more. The response time of your web hosting depends on the quality of its network and hardware. Ultimately, server response time is the foundation of your website's speed. According to Google, a server response speed of **200 ms** is your goal. Learn more about [how our Server Speed Checker works](#).

and assign a rating to it. The map at the right hand side shows the whereabouts of our testing servers. Click on it for a larger map.

1. In using Bitcatcha Server Speed Checker, the ideal rating is B+ and above. At minimum it should be C+. Due to the nature of how computer networking works, the test depends largely on network stability across the globe, which means the result can vary at different times because it's almost impossible for a network to be 100 percent stable. We encourage you to repeat the test at various times to see the difference it makes.

1. If your rating has not improved to at least C+ after a few tests, we suggest you review the locations where your server performs poorly. If your targeted audience is not in the affected locations, this issue probably won't matter. Otherwise user experience will suffer when your website loads slowly at those locations. This may result in a loss of users and sales. In that case we strongly suggest you switch host providers to one who performs better in the affected locations.
